

Dermat's Guide

WHY IS YOUR ACNE NOT GOING AWAY?

(The 3 Hidden Reasons)

1

REASON 1: THE 8-WEEK RULE

- The Science: A "micro-pimple" takes about 8 weeks to form under your skin.
- The Reality: Medical-grade creams (like Retinoids) don't work overnight. In fact, your skin might look a little red or "purge" in the first 2 weeks.
- The Rule: You must give any new treatment at least 2 to 3 months before deciding if it works. Consistency beats intensity!

2

THE "SINGLE CREAM" MISTAKE (ANTIBIOTIC RESISTANCE)

Using just an antibiotic cream (like Clindamycin) for months is a recipe for failure.

- **The Science:** The bacteria that cause acne (*C. acnes*) are smart. If you use the same antibiotic for too long, they learn how to "beat" it.
- **The Fix:** This is why we always pair antibiotics with Benzoyl Peroxide. It's like a backup force that prevents the bacteria from becoming resistant, making your treatment much more powerful.

THE "HIDDEN STEROID" DANGER

This is a huge problem in India. Many "fairness" or "miracle" creams bought over-the-counter contain hidden steroids.

- The Danger: These creams give you a temporary glow but actually thin your skin and cause "Steroid-Induced Acne."
- The Reality: If you've been self-medicating with "triple action" creams, you might be damaging your skin barrier, making it impossible for real acne medication to work.

SEE A DERMATOLOGIST

Acne needs a treatment plan,
not random products

Consult a dermatologist for the
right approach.
